# Kintsu

## A Stellar wallet with no single point of failure: distributed backups and 2FA for spending.

# Self-custody fails in two ways.

01 — LOST KEYS

## People lose access

A seed phrase gets lost, thrown away or burned. A phone breaks or is stolen. The money is gone for good.

02 — HACKED

## People get hacked

Phone wallets and browser extensions hold the whole key. One compromised device can spend everything.

**Both come from one flaw: a single point of failure.**

# Why now: AI makes every online device a target.

JULY 2026 · COLDCARD

## A firmware bug made keys guessable

A weak random number generator let attackers drain thousands of wallets. Users who had added their own dice rolls were not affected.

THE LESSON

## Two rules

1. Keys should come from the user, not only from a device.

2. Spending should need two separate devices, one of them offline.

**Kintsu is built on both rules.**

# No single point of failure.

## Distributed backups

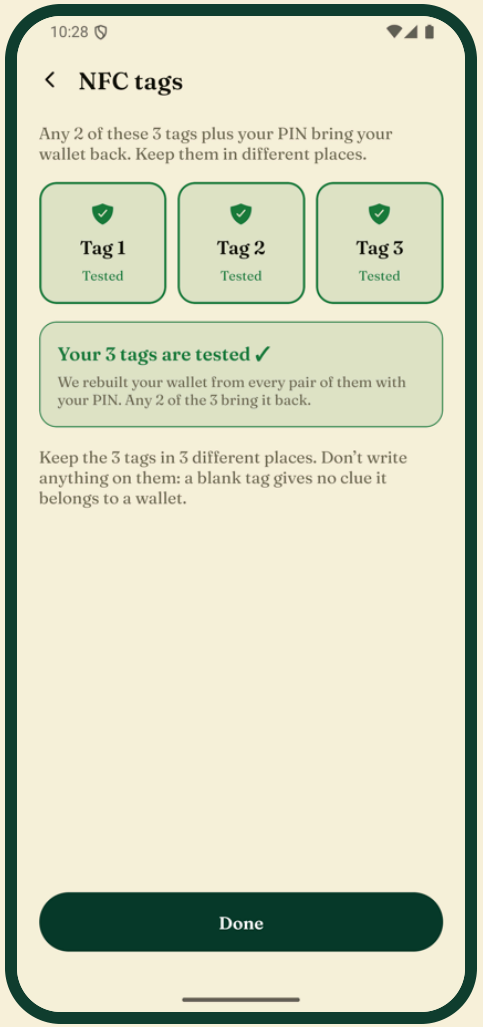

The wallet is split across 3 NFC tags kept in 3 places. Any 2 plus a PIN bring it back; one alone reveals nothing. Paper is there too, if you want it.

## 2FA for spending

Every payment needs the phone and a tap of an offline 2FA device. A hacked or stolen phone can’t spend.

## Keys from you

Create the wallet from your own dice rolls or camera photos.

# Who can do what

| TO… | YOU NEED | NOT ENOUGH ON ITS OWN |
|---|---|---|
| **Send or swap money** | **Phone + 2FA tap** | A stolen phone. A lost 2FA device. |
| **Change who controls the wallet** | **2 tags + PIN** | The phone and the 2FA device together. |
| **Recover a lost phone** | **2 tags + PIN** | One tag. The old phone is locked out. |

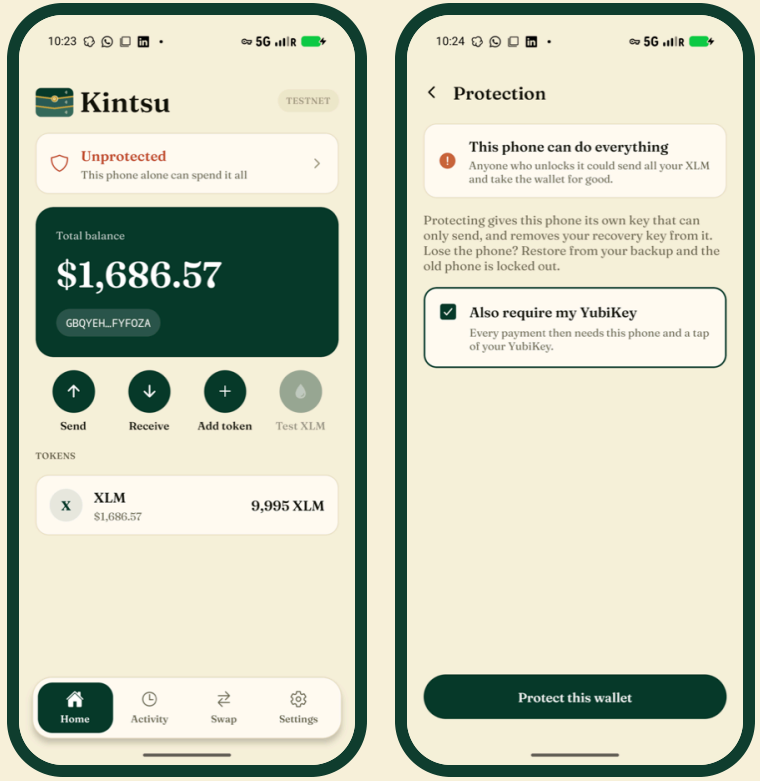

**Enforced by Stellar itself: no smart contract, no server, no custodian.** WHY STELLAR

# Working today, on testnet and mainnet.

**Built in 28 hours** at HackMeridian, tested with a real Pixel, real NFC tags and a YubiKey

**Stellar native:** multi-signature accounts, built-in exchange, USDC and EURC

**Audited crypto libraries only;** Android APK on GitHub for judges

**Try it: the APK runs without tags or a key, simulated.**

# Business model

HARDWARE

## The Kintsu kit

3 tags and an offline key, sold together. Tags cost cents; the kit is the product people buy.

USAGE

## Swap fee

A small fee on swaps through Stellar's built-in exchange.

PARTNERS

## White-label

Stellar wallets and anchors add tag backup and hardware approval for their users.

**Open-source app. Revenue from the kit, swaps and partners.**

# Next 3 months

1

## Security audit

Before real savings go in.

2

## Mainnet launch

With the first 100 users and kits.

3

## iPhone

NTAG216 tags, readable on iOS.

**The ask: an SCF Build award to fund the audit and launch.**
